

Answers to Question 2:

- a) In March 2023, I developed models to trade commodities futures markets based exclusively on binning. For each variable in my historical dataset, I used Python packages like optbinning to best describe the relationship between that variable and market price. Then, I created ensembles of several variables that seemed to have a monotonic relationship with price when tested against hold-out (unseen) data. I generated backtests based on hypothetical results to confirm commercial feasibility. And then, I made the worst decision of my career - I decided to use these models to actually trade the markets. As you can probably guess, these models failed to perform when subjected to live data.
- b) Mystery.
- c) A Parking Valet or Uber driver.
